In this article we construct all kinds of elementary Prym differentials for arbitrary characters on a variable torus with a finite numbers of punctures and find the dimensions of two important quotient spaces. As a consequence, this yields the dimension of the first holomorphic de Rham cohomology group of Prym differentials for arbitrary characters on torus. Also, we construct explicit bases in these quotient spaces.

Keywords: Prym differentials for arbitrary characters, the Gunning cohomological bundle over the Teichmuller space torus with a finite numbers of punctures.

Introduction

The theory of multiplicative functions and Prym differentials in the case of special characters on a compact Riemann surface has found applications in the geometric function theory of complex variable, the analytic number theory and in the mathematical physics [1–7]. In [1–3] the development of the general theory of multiplicative functions and Prym differentials on a compact Riemann surface of genus $g \geq 2$ for arbitrary characters has been started. The function theory on compact Riemann surfaces differs substantially from that on finite Riemann surfaces even for the class of single-valued meromorphic functions and abelian differentials. A number of basic spaces of functions and differentials on a finite Riemann surface $F'$ of type $(g, m)$, with $g \geq 1, m > 0$, are infinite-dimensional.

In this article we start constructing the general function theory on a variable torus with a finite numbers of punctures for multiplicative meromorphic functions and differentials with arbitrary characters. We construct all kinds of elementary Prym differentials for arbitrary characters on such surfaces and find the dimensions of two important quotient spaces. As a consequence, this yields the dimension of the first holomorphic de Rham cohomology group of Prym differentials for arbitrary characters on torus. Also, we construct explicit bases in these quotient spaces.

1. Preliminaries

Fix a smooth compact oriented surface $F$ of genus $g = 1$, with a marking $\{a, b\}$, which is an ordered tuple of generators for $\pi_1(F)$. Let $F_0$ be a fixed complex analytic structure on $F$. From now on, for brevity, the Riemann surface $(F; F_0)$ will be denoted by $F_0$. Fix distinct points $P_1, \ldots, P_m \in F$. Suppose that $F' = F\{P_1, \ldots, P_m\}$ is a surface of type $(1, m)$, with $m \geq 1$. Denote by $\Gamma'$ the Fuchsian group of the first kind that acts invariantly on the disk $U = \{z \in \mathbb{C} : |z| < 1\}$ and uniformizes the surface $F'_0$, i.e. $F'_0$ is conformally equivalent to $U/\Gamma'$. This group has the representation $\Gamma' = \langle A, B, \gamma_1, \ldots, \gamma_m : [A, B]\gamma_1 \ldots \gamma_m = I \rangle$, where $[A, B] = ABA^{-1}B^{-1}$ for $A, B \in \Gamma'$, and $I$ is the identity mapping [6].

Every complex analytic structure on $F'$ is determined by some Beltrami differential $\mu$ on $F'_0$; i.e., an expression of the form $\mu(z)dz/d\bar{z}$ independent of the choice of a local parameter on $F'_0$, where $\mu(z)$ is a complex function on $F'_0$ and $|\mu|_{L^\infty(F'_0)} < 1$. Denote this structure on $F'$ by $F'_\mu$. It is clear that $\mu = 0$ corresponds to $F'_0$. Let $M(F')$ be the set of all complex analytic structures on $F'$ endowed with the topology of $C^\infty$ convergence on $F'_0$. $Diff^+(F')$ be the group of all orientation-preserving smooth diffeomorphisms of $F'$ leaving all punctures fixed, and $Diff_0(F')$ be the normal subgroup of $Diff^+(F')$ consisting of all diffeomorphisms homotopic to the identity diffeomorphism of $F'_0$. Then the Teichmüller space $T_{1,m}(F') = T_{1,m}(F'_0)$ is the quotient space $M(F')/Diff_0(F')$ [6].

Since the mapping $U \to F'_0 = U/\Gamma'$ is a local diffeomorphism, every Beltrami differential $\mu$ on $F'_0$ lifts to a Beltrami $\Gamma'$-differential $\mu$ on $U$; thus, $\mu \in L^\infty(U)$, $|\mu|_{L^\infty(U)} = \text{ess} \{\mu(z)\} < 1$, and $\mu(\hat{T}(z))/\hat{T}'(z) = \mu(z)$, $z \in U$, $T \in \Gamma'$.

Extend the $\Gamma'$-differential $\mu$ on $U$ to $\hat{\mathbb{C}} \cup U$ by putting $\mu = 0$. Then there exists a unique quasiconformal homeomorphism $w^\mu : \mathbb{C} \to \hat{\mathbb{C}}$ with fixed points $+1, -1, i$, which is a solution to the Beltrami equation $\omega^\mu = \mu(z) w_z$. The mapping $T \to \hat{T}_\mu = w^\mu T(w^\mu)^{-1}$ determines an isomorphism of $\Gamma'$ onto the quasi-Fuchsian group $\Gamma'_\mu = w^\mu \Gamma(w^\mu)^{-1} = \langle A^\mu, B^\mu, \gamma^\mu_1, \ldots, \gamma^\mu_m : [A^\mu, B^\mu] \gamma^\mu_1 \ldots \gamma^\mu_m = I \rangle$.

The classical results of Ahlfors and Bers [6], and other authors assert that

1) $T_{1,m}(F')$ is a complex manifold of dimension $m$ for $m \geq 1$; 2) $T_{1,m}(F')$ carries a unique complex analytic structure such that the natural mapping $\Psi : M(F') \to T_{1,m}(F')$ is holomorphic; furthermore, $\Psi$ has only local holomorphic sections; 3) the elements of $\Gamma'_\mu$ depend holomorphically on the moduli $[\mu]$ of finite Riemann surfaces $F'_\mu$.

Two Beltrami $\Gamma'$-differentials $\mu$ and $\nu$ are conformally equivalent if and only if $w^\mu T(w^\mu)^{-1} = w^\nu T(w^\nu)^{-1}$, with $T \in \Gamma'$. It is natural that the choice of generators $\{a, b\} \cup \{\gamma_1, \ldots, \gamma_m\}$ in $\pi_1(F')$ is equivalent to the choice of a systems of generators $\{w^\mu, b^\mu\} \cup \{\gamma^\mu_1, \ldots, \gamma^\mu_m\}$ in $\pi_1(F'_\mu)$, and $\{A^\mu, B^\mu\} \cup \{\gamma^\mu_1, \ldots, \gamma^\mu_m\}$ in $\Gamma'_\mu$ for every $[\mu]$ in $T_{1,m}$. This implies the identifications $M(F')/Diff_0(F') = T_{1,m}(F') = T_{1,m}(\Gamma')$. Furthermore, there is a bijective correspondence between the classes of Beltrami differentials $[\mu]$, the classes of conformally equivalent marked finite Riemann surfaces $[F'_\mu; \{a^\mu, b^\mu\} \cup \{\gamma^\mu_1, \ldots, \gamma^\mu_m\}]$ and marked quasi-Fuchsian groups $\Gamma'_\mu$ [5, 6].

In [6, p. 99] Bers constructed a holomorphic abelian differential $\zeta[\mu] = dz$ on $F'_\mu$ for every $[\mu] \in T_1$, with the condition $\int_{A^\mu(\xi)} \zeta(\mu, w)dw = 1$, $\xi \in \mathbb{C}$, and it depends holomorphically on the moduli $[\mu]$ for $F'_\mu$. Moreover, the $b$-period on $F'_\mu$ is the complex number $b = \int_{B^\mu(\xi)} \zeta(\mu, w)dw, \xi \in \mathbb{C}$, and it depends holomorphically on the moduli $[\mu]$.

Define for arbitrary fixed $[\mu] \in T_1$ and $\xi_0 \in \mathbb{C}$ the classical Jacobi mapping $\varphi : \mathbb{C} \to \mathbb{C}$ by $\varphi(\xi) = \int_{\xi_0}^\xi \zeta(\mu, w)dw$. The quotient space $J(F'_\mu) = \mathbb{C}/L(F'_\mu)$ is called the marked Jacobian variety for $F'_\mu$, where $L(F'_\mu)$ is the lattice over $\mathbb{Z}$ generated by the elements 1 and $\mu$. The universal Jacobian variety for torus is a fibration over $\mathbb{T}_1$, whose fiber over $[\mu] \in T_1$ is the Jacobian $J(F'_\mu)$ of the surface $F'_\mu$ [5, 7].

Next, given an integer $n > 1$, there exists a fibration over $\mathbb{T}_1$ whose fiber over $[\mu] \in T_1$ is the space of all degree $n$ integer divisors on $F'_\mu$. The holomorphic sections of this bundle determine on every $F'_\mu$ a degree $n$ integer divisor $D^\mu$, which holomorphically depends on $[\mu]$. Also there exists a holomorphic mapping $\varphi_n$ from this bundle into the universal Jacobian bundle, $n \geq 1$, whose restriction to the fibres extends the Jacobi mapping $\varphi : F'_\mu \to J(F'_\mu) \cong F'_\mu$. We can obtain local holomorphic sections of these bundles over a neighborhood $U([\mu_0]) \subset T_1$ (for every $n \geq 1$) from local holomorphic sections $s$ of $\Psi : M(F') \to \mathbb{T}_1$ over $U([\mu_0])$ [7].
A character \( \rho \) for \( F'_\mu \) is every homomorphism \( \rho : (\pi_1(F'_\mu), \cdot) \to (C^*, \cdot) \). Each character is uniquely determined by an ordered tuple \( (\rho(a^\mu), \rho(b^\mu), \rho(\gamma^\mu_1), \ldots, \rho(\gamma^\mu_m)) \) in \((C^*)^{2+m}\).

**Definition 1.1.** A multiplicative function \( f \) on \( F'_\mu \) for a character \( \rho \) is a meromorphic function \( f \) on \( w^\mu(U) \) such that \( f(Tz) = \rho(T)f(z) \), \( z \in w^\mu(U) \), \( T \in \Gamma'_\mu \).

**Definition 1.2.** A Prym \( q \)-differential with respect to a Fuchsian group \( \Gamma' \) for \( \rho \), or \((\rho, q)\)-differential, is a differential \( \omega(z)dz^q \) such that \( \omega(Tz)(T'^qz)^q = \rho(T)\omega(z) \), \( z \in U \), \( T \in \Gamma' \), \( \rho : \Gamma' \to C^* \), \( q \in \mathbb{N} \).

If \( f_0 \) is a multiplicative function on \( F'_\mu \) for \( \rho \) without zeros and poles then \( f_0(P) = f_0(P_0) \exp \int_{P_0[\mu]} 2\pi ic([\mu], \rho)\zeta([\mu]), \) where \( P_0[\mu] = f^\mu[\mu](P_0) \in F'_\mu \), \( c([\mu], \rho) \in C \), \( c \) depend holomorphically on \([\mu] \) and \( \rho \). Furthermore, integration is performed from a fixed point \( P_0[\mu] \) to the current point \( P \) on the variable surface \( F'_\mu \), and \( s[\mu] \) is the Earle section [7] over \( U(\mu) \subset T_1 \).

We deduce that the character \( \rho \) for \( f_0 \) is of the form \( \rho(a^\mu) = \exp 2\pi ic([\mu], \rho), \rho(b^\mu) = \exp 2\pi ic([\mu], \rho) \). Refer to these characters \( \rho \) as unessential, while to \( f_0 \) with this character, as a unit. The characters which are not unessential we call essential on \( \pi_1(F'_\mu) \). Denote by \( Hom(\Gamma, C^*) \) the group of all characters on \( \Gamma \) with the natural multiplication. The unessential characters constitute a subgroup \( L_1 \) of \( Hom(\Gamma, C^*) \) [1].

**Definition 1.3.** \( \phi \) on \( F' = U/\Gamma' \) for \( \rho \) is called multiplicatively exact, whenever \( \phi \) is a differential \( f(z) \) and \( f(Tz) = \rho(T)f(z) \), \( T \in \Gamma', z \in U \); thus, \( f \) is a multiplicative function on \( F' \) for \( \rho \).

Given \( \rho \in Hom(\Gamma'_\mu, C^*) \), denote by \( Z^1(\Gamma'_\mu, \rho) \) the set of all mappings \( \phi : \Gamma'_\mu \to C \) such that \( \phi(ST) = \phi(S) + \rho(S)\phi(T), S, T \in \Gamma'_\mu \) [1].

Let \( \phi \) be a closed Prym differential on \( F'_0 \) for \( \rho \). Integrating this differential, we obtain \( f(Tz) - f(Tz_0) = \rho(T)(f(z) - f(z_0)) \), where \( f = df(z) \), \( z \in U \), \( f(z) \) is a Prym integral on the disk \( U \) for \( \phi \), which is determined up to an additive term. Hence, \( T \in \Gamma' \) satisfies \( f(Tz) = \rho(T)f(z) + \phi_f(z_0)(T), \phi_f(z_0)(T) = f(Tz_0) - \rho(T)f(z_0) \). Therefore, the period mapping \( \phi_f : \Gamma' \to C \) for \( \phi \) is defined. It depends on the choice of a Prym integral \( f(z) \) on \( U \) and a base point \( z_0 \). Given another Prym integral \( f(z) = f(z) + c \) for \( \phi \), we have \( \phi_f(z_0)(T) = \phi_f(z)(T) + c(T), \sigma(T) = 1 - \rho(T), T \in \Gamma' \). It is easy to verify that both mappings \( \phi_f(z_0) \) and \( \phi_f(z_0)(T) \) satisfy the cocycle relation \( \phi(ST) = \phi(S) + \rho(S)\phi(T), S, T \in \Gamma' \). They belong to the space \( Z^1(\Gamma', \rho) \) and represent the same class of periods \( [\phi] \) in \( H^1(\Gamma', \rho) = Z^1(\Gamma', \rho)/B^1(\Gamma', \rho) \) for the Prym differential \( \phi \) for \( \rho \) on \( F' \), where \( B^1(\Gamma', \rho) \) is generated by \( \sigma \).

For a closed Prym differential \( \phi \) we can determine the classical periods. For \( T \in \Gamma' \) the corresponding classical period \( \phi_{z_0}(T) = \int_{z_0}^{Tz_0} \phi \) and we have the equality \( \phi_{z_0}(T) = \phi_f(z)(T) - f(z_0)\sigma(T) \).

Consequently, the mappings of the form \( T \to \phi_{f,z_0}(T) \) (periods in the sense of Gunning) and of the form \( T \to \phi_{z_0}(T) \) (the classical periods) determine the same class of periods \( [\phi] \in H^1(\Gamma', \rho) \) for a Prym differential \( \phi \) on \( F' \) for \( \rho \). Thus, we have a well-defined \( C \)-linear mapping \( \rho : \phi \to [\phi] \) from the vector space of closed Prym differentials \( \phi \) on \( F' \) for \( \rho \) in the vector space \( H^1(\Gamma', \rho) \).

Denote by \( \Omega_{2,\rho}(F'_\mu) \) the space of Prym differentials of the second kind with finitely many poles on \( F'_\mu \) for character \( \rho [5, 2] \). The space \( A_1(\rho) \) consists of Prym differentials for \( \rho \) on \( F' \) that have finitely many poles on \( F' \) and extend meromorphically on \( F \).

**Lemma 1.1.** If the differential \( \omega \in \Omega_{2,\rho}(F'_\mu) \cap A_1(\rho) \) has the class of periods \( [\omega] = 0 \) in \( H^1(\Gamma'_\mu, \rho) \), then \( \omega \) is a multiplicatively exact differential on \( F'_\mu \) for \( \rho \).

**Proof.** It suffices to verify this for a fixed surface and a fixed character. We obtain the classical periods \( \gamma_1, \ldots, \gamma_k \) while going separately around the poles \( Q_1, \ldots, Q_k \) of the differential \( \omega \). They
all vanish, being equal to the residues at the poles of second or higher order for the branches of our multivalued differential ω the second kind.

If the class of periods [ω] = 0, then the classical period ω_{z_0}(T) = σ(T), c ≠ 0 for every T, where ω_{z_0}(T) = f(T_{z_0}) − f(z_0) = c(1 − ρ(T)), while f is some Prym integral for ω. Then \( \tilde{f} = (f − c) \) is a multiplicative function for ρ and \( ω = d\tilde{f} = d(f − c) \). Thus, the periods \( \tilde{ω}_{z_0}(a), \tilde{ω}_{z_0}(b), \tilde{ω}_{z_0}(γ_1), ..., \tilde{ω}_{z_0}(γ_m) \) in the sense of Gunning all vanish for some representative of class [ω]. Consequently, ω is a multiplicatively exact differential for ρ on \( F_µ \). The proof of Lemma 1.1 is complete.

A divisor on \( F_µ \) is a formal product \( D = P_1^{m_1} ... P_k^{m_k}, P_j ∈ F_µ, m_j ∈ Z, j = 1, ..., k \).

**Theorem** (Riemann-Roch’s theorem for characters \([5, 2]\)). Let \( F \) be a compact Riemann surface of genus one. Then for every divisor \( D \) on \( F \) and every character \( ρ \) the equality \( r_ρ(D^{-1}) = \deg D + \#(D) \) holds.

**Theorem** (Abel’s theorem for characters \([5, 2]\)). Let \( D \) be a divisor on a marked variable compact Riemann surface \([F_µ, \{µ^κ, b^κ\}]\) of genus one and \( ρ \) a character on \( π_1(F_µ) \). Then \( D \) is a divisor of a multiplicative function \( f \) on \( F_µ \) for \( ρ \Leftrightarrow \deg D = 0 \) and

\[
φ(D) = \frac{1}{2πi} \log ρ(b^κ) − \frac{1}{2πi} \mu \log ρ(a^κ)(≡ ψ(ρ, [μ]))
\]

in \( C \) modulo the integer lattice \( L(F_µ) \) generated by the complex numbers \( 1, \mu \).

Observe that by a theorem of Bers [6, p.99], the mapping \( ψ \) depends locally holomorphically on \( ρ \) and \([μ]\).

Every element \( φ ∈ Z^1(Γ^*') \) is unique determined by the ordered tuple of complex numbers \( φ(A), φ(B), φ(γ_1), ..., φ(γ_m) \).

**Lemma 1.2** ([8]). For every \( φ ∈ Z^1(Γ^*', ρ) \) there holds the equality

\[
σ(B)φ(A) − σ(A)φ(B) + φ(γ_1) + \sum_{j=1}^{m-1} ρ(γ_1 ... γ_j)φ(γ_{j+1}) = 0.
\]

**Lemma 1.3** ([8]). The holomorphic principal \( Hom(Γ^*, C^*)\)-bundle \( E = \bigsqcup_{[μ]} Hom(Γ^*', C^*) \) is analytically equivalent to the trivial bundle \( T_{1,m}(F') × Hom(Γ^*, C^*) \) over the base \( T_{1,m}(F') \).

The set \( G' = \bigcup_{[μ], ρ \neq 1} H^1(Γ^*, ρ) \) is called the Gunning cohomological bundle over the base \( T_{1,m} × Hom(Γ^*, C^*) \setminus \{1\} \). For \( G' \) and \( ρ \neq 1 \) we use Gunning’s isomorphism [1] between the complex vector space \( H^1(Γ^*, ρ) \) and the vector space \( Hom_ρ(Γ^*, C) \), which consists of homomorphisms \( φ_0 : \{Γ^*_ρ, Γ^*\} \to (C, +) \) with the condition \( φ_0(STM^{-1}) = ρ(S)φ_0(T), T ∈ [Γ^*_ρ, Γ^*], S ∈ Γ^* \). Here \( [Γ^*_ρ, Γ^*] \) is the commutant group \( Γ^* \). Thus, the bundle \( G' \) is isomorphic to the vector bundle \( \bigcup_{[μ], ρ \neq 1} Hom_ρ([Γ^*_ρ, Γ^*], C) \).

Moreover, we can determine the transition matrices of this bundle in terms of two coordinate neighborhoods \( U_i = \{ρ : σ(A) \neq 1\}, U_2 = \{ρ : σ(B) \neq 1\} \), which cover the base \( Hom(Γ^*, C^*) \setminus \{1\} \) provided that \( ρ(γ_j) = 1, j = 1, ..., m \). For the neighborhood \( U_1 \) we have \( σ(A^ρ) ≠ 0 \). Every element \( φ_0 ∈ Hom_ρ([Γ^*_ρ, Γ^*], C) \) for \( ρ ∈ U_1 \) can be defined as \( φ_0 = φ_0^1|Γ^*_ρ, Γ^* \) for \( φ_0^1 ∈ Z^1(Γ^*_ρ, ρ) \) such that \( φ_1(A^ρ) = 0 \) and \( φ_1(T) = σ(A^ρ)^{-1}φ_0([T, A^ρ]), T ∈ Γ^* \).

**Theorem** ([1, 8]). The Gunning cohomological bundle \( G' \) over \( T_{1,m}(F') × Hom(Γ^*, C^*) \setminus \{1\} \) is a holomorphic vector bundle of rank \( m \) for \( m ≥ 1 \).
2. Elementary Prym differentials

In the construction of a general theory of single-valued and multiplicative differentials, an important role is played by the elementary differentials [3, 5] of arbitrary order with the minimal number of poles, either one pole of order $\geq 1$, or two simple poles, depending holomorphically on the character $\rho$ and the moduli $[\mu]$ of Riemann surfaces. In this section we find the general form of elementary $(\rho, q)$-differentials on $F'_\mu$.

Proposition 2.1 ([2]). A degree 0 divisor $D$ is a divisor of a meromorphic $(\rho, q)$-differential $\omega$ on a compact Riemann surface $F$ of genus $g = 1$ for a character $\rho$ with $q \geq 1$ if and only if $\varphi(D) = \psi(\rho)$ in $J(F)$.

The proof proceeds as in the case $q = 1$ considered in [3, 5], taking into account that $-2K = 0$ in $J(F)$ for the torus $F$.

Theorem 2.1. Given a point $Q$, a character $\rho$ on $F'_\mu$ of type $(1, m)$, $m \geq 1$, and natural numbers $n \geq 2$, $q \geq 1$ there exists an elementary $(\rho, q)$-differential $\tau^{(n)}_{\rho, q; Q}$ of the class $\mathbf{A}_1(\rho)$ with a unique pole $Q$ of order exactly $n$ on $F'_\mu$. The general form of its divisor is $(\tau^{(n)}_{\rho, q; Q}) = \frac{R_1 ... R_N}{Q^n \cdot P_1^{q_1} ... P_m^{q_m}}$, where $\varphi(R_i) = \varphi(Q^n) - \varphi(R_1 ... R_N) + \varphi(P_1^{k_1} ... P_m^{k_m}) + \psi(\rho)$, $k_j \geq 0$, $j = 1, \ldots, m$. The points $R_1, \ldots, R_N$ are chosen as a local holomorphic section of divisors of degree $N - 1$ on $F'_\mu$, and $N = n + k_1 + \cdots + k_m$. Moreover, these differentials depend locally holomorphically on $[\mu]$ and $\rho$, and for an essential character we have $\tau^{(n)}_{\rho, q; Q} = \left(\sum_{j=1}^{\infty} + O(1)\right) dz^q, z(Q) = 0$.

Proof. Given $q \geq 1$, find the general form of $(\rho, q)$-differentials of the second kind with a unique pole at the point $Q$ of order exactly $n \geq 1$ on $F'_\mu$.

The Riemann-Roch theorem for $(\rho, q)$-differentials on $F'_\mu$ [3] yields the dimension

\[
i_{\rho, q} \left(\frac{1}{Q^n \cdot P_1^{q_1} ... P_m^{q_m}}\right) = \dim \Omega^2 \left(\frac{1}{Q^n \cdot P_1^{q_1} ... P_m^{q_m}}\right), \text{ where } k_j \geq 0, j = 1, \ldots, m.\]

We have $i_{\rho, q}(D) = -\deg D + r\left(\frac{f[\mu]}{D}\right)$, where $D = \frac{1}{Q^n \cdot P_1^{q_1} ... P_m^{q_m}}$, $f[\mu]$ is an arbitrary multiplicative function for $\rho$ on $F'_\mu$, which locally holomorphically depends on $[\mu]$ and $\rho$ [3]. Hence $i_{\rho, q} \left(\frac{1}{Q^n \cdot P_1^{q_1} ... P_m^{q_m}}\right) = n + k_1 + \cdots + k_m \geq 1$. Here $r\left(\frac{f[\mu]}{D}\right) = 0$, since $\deg \left(\frac{f[\mu]}{D}\right) > 0$ under our assumptions. Indeed, $\deg(f[\mu]) = 0$ and $\deg(D) \geq m > 0$. We can prove this fact in a different way. If there exists a function $g \neq 0$ for $\rho$ on $F'_\mu$ satisfying $(g) \geq Q^n \cdot P_1^{q_1} ... P_m^{q_m} (f[\mu])$, then $0 = \deg(g) \geq \deg(Q^n \cdot P_1^{q_1} ... P_m^{q_m} (f[\mu])) \geq 2$; this is a contradiction.

It is clear that $i_{\rho, q} \left(\frac{1}{Q^{q_1} ... P_1^{q_1} ... P_m^{q_m}}\right) = i_{\rho, q} \left(\frac{1}{Q^{q_1} ... P_1^{q_1} ... P_m^{q_m}}\right) + 1$. Consequently, there exists a $(\rho, q)$-differential $\frac{1}{\tau^{(n)}_{\rho, q; Q}}$ with a pole of order exactly $n$ at the point $Q$ on $F'_\mu$. Therefore,

\[
\tau^{(n)}_{\rho, q; Q} = \frac{R_1 ... R_N}{Q^n \cdot P_1^{q_1} ... P_m^{q_m}} \text{ on } F'_\mu. \text{ Thus } (\tau^{(n)}_{\rho, q; Q}) = R_1 ... R_N \text{ on } F'_\mu.
\]

These $(\rho, q)$-differentials $\omega = \tau^{(n)}_{\rho, q; Q}$ from $\mathbf{A}_1(\rho)$ onto $F'_\mu$ are determined non uniquely on $F'_\mu$ because of their zeros and poles: $\omega = \frac{R_1 ... R_N}{Q^n \cdot P_1^{q_1} ... P_m^{q_m}}$, $k_j \geq 0$, $j = 1, \ldots, m$. Fix $k_1, \ldots, k_m$, as the orders of possible poles at the points $P_1, \ldots, P_m$. Furthermore, $\deg(\omega) = 0$ on $F'_\mu$. This implies that $N = n + k_1 + \cdots + k_m$.

Proposition 2.1 yields the equation $\varphi(P_0(R_1 ... R_N) - \varphi(P_0(Q^n)) - \varphi(P_0(P_1^{k_1} ... P_m^{k_m})) = \psi(\rho)$ in the Jacobian variety $J(F'_\mu)$. Consequently, $\varphi(R_1 ... R_N) = \varphi(Q^n) + k_1 \varphi(P_1) + \cdots + k_m \varphi(P_m) + \psi(\rho) = M$ or $\varphi(R_1) = M - \varphi(R_2 ... R_N)$. Therefore, to specify the zeros of the differential we have $N - 1 = n + k_1 + \cdots + k_m \geq 1$, for $k_1 \geq 1$, free parameters which can choose arbitrarily.
on $F'_\mu$. Solving the Jacobi inversion problem, we find $R_1$, which is the unique holomorphic solution to the equation.

Show now that the point $Q$ is a pole of order exactly $n$ on $F'_\mu$. The proof is by contradiction. Assume that only first points $R_1, \ldots, R_k$, $k \leq n$, coincide with $Q$ on $F'_\mu$. Then we have the equality

$$\varphi(R_{k+1}) = \varphi(Q^{n-k}) + \psi(\rho) + k_1\varphi(P_1) + \cdots + k_m\varphi(P_m) - \varphi(R_{k+2} \ldots R_N) = \widetilde{M}. \quad (*)$$

Choosing the point $R_{k+1} \in F'_\mu$ such that $\varphi(R_{k+1})$ is not equal to the constant $\widetilde{M}$ and the point $R_{k+1}$ is not $Q$, we have the contradiction. Thus, the point $Q$ is indeed a pole of order exactly $n$ on $F'_\mu$.

Consequently, the divisor $(\varphi^{(n)}) = \frac{R_1}{Q_1} \frac{R_2}{Q_2} \ldots \frac{R_N}{Q_N}$ has the most general form for the $(\rho, q)$-differentials $\varphi^{(n)}$ of class $A_1(\rho)$ with a unique pole $Q \in F'_\mu$ exactly of order $n \geq 2$ on $F'_\mu = F'_\mu \{P_1, \ldots, P_m\}$. By induction on $n$, taking into account the case $n = 1$ and an essential character $\rho$ [8], we have $\tau^{(n)}_{\rho,q} Q = \left(\frac{1}{2} + O(1)\right)dz^q$.

The proof of Theorem 2.1 is complete. \qed

We can prove the next statement in the same fashion.

**Theorem 2.2.** Given distinct points $Q_1, Q_2$ on a surface $F'_\mu$ of type $(1, m), m \geq 1$, a character $\rho$ on $F'_\mu$ and a natural number $q \geq 1$, there exists an elementary $(\rho, q)$-differential $\tau_{\rho,q,Q_1Q_2}$ of the third kind and class $A_1(\rho)$, with exactly simple poles $Q_1$ and $Q_2$ on $F'_\mu$, with the general form of divisor $(\tau^{(n)}_{\rho,q,Q_1Q_2}) = \frac{R_1 \ldots R_N}{Q_1^{n_1} \ldots Q_N^{n_n}}$, where $\varphi(R_1) = \varphi(Q_1Q_2) - \varphi(R_2 \ldots R_N) + \varphi(P_{1k}^{(1)}) + \cdots + \varphi(P_{mk}^{(m)}) + \psi(\rho)$, $k_j \geq 0$, $j = 1, \ldots, m$. Furthermore, we choose the points $R_2, \ldots, R_N$ as locally holomorphic section of divisors of degree $N - 1$ on $F'_\mu \{Q_1, Q_2\}$, $N = 2 + k_1 + \cdots + k_m$. Also, these differentials depend locally holomorphically on $[\mu]$.\rho and $\rho$.

## 3. Prym differentials for an unessential characters

Given a character $\rho$, denote by $\Omega_{2,\rho}(F'_\mu)$ the space of meromorphic differentials of the second kind with finitely many poles on $F'_\mu$, and by $\Omega_{c,\rho}(F'_\mu)$, the subspace of all multiplicatively exact Prym differentials for $\rho$ on $F'_\mu$. Let $\tau^{(n)}_{\rho}$ be an abelian differential of the second kind on $F'_\mu$ with a unique pole of order exactly $n \geq 2$ at the point $\tilde{P}_1$, and with zero $a$-periods [5]. The point $\tilde{P}_1$ is chosen using the condition $r_{\rho}(\frac{1}{\tilde{P}_1}) = 1$.

For every character $\rho \neq 1$ define the mapping from $\Omega_{2,\rho}(F'_\mu)$ into $H^1(T'_\mu, \rho)$, associating to a differential $\omega$ its class of periods $[\omega]$.

Suppose that $\omega \in \Omega_{2,\rho}(F'_\mu)$ lifts to $U$, where $F'_\mu = U/\tilde{\Gamma}$, and $\tilde{\Gamma}$ is the Fuchsian group of the first kind uniformizing $F'_\mu$ on $U$ [2, 6]. Find the classical periods $\omega_{j\nu}(T) = \int_{z_0}^{T_{20}} \omega + n_{j
u} \int_{\gamma_{m+1}}^{T_{20}} \omega + \cdots + n_{j+k} \int_{\gamma_{m+k}}^{T_{20}} \omega$, where $n_j \in \mathbb{Z}$, $j = m + 1, \ldots, m + k$. Here $\gamma_{m+1}, \ldots, \gamma_{m+k}$ stand for loops enclosing only the poles $Q_1, \ldots, Q_k$ of $\omega$ on $F'_\mu$ respectively. We take the integral $\int_{z_0}^{T_{20}} \omega$ along some fixed particular path in the disk $U$ avoiding the poles of $\omega$.

Since $\omega$ is a differential of the second kind, all residues at its poles vanish. Thus, there exists a global primitive, a meromorphic function $f(z)$ on $U$ satisfying $\omega = df$ on $F'_\mu \{Q_1, \ldots, Q_k\}$.

Lifting now $\omega = df$ to $U$, relative to $\tilde{\Gamma}$, we obtain $\omega_{j\nu}(T) = \int_{z_0}^{T_{20}} df(z)$ for every $T \in \tilde{\Gamma}$, where $\tilde{\Gamma}$.
is the Fuchsian group of the first kind on $U$ normalizing the surface $F'_\mu$, which results from $F'_\mu$ by removing all $k$ poles $Q_1, \ldots, Q_k$ of the differentials $\omega$.

Define the mapping

$$\Omega_{2,\rho}(F'_\mu) \ni \omega \mapsto [\omega] = \{\omega_{2\alpha}(A), \omega_{2\beta}(B), \omega_{2\gamma}(\gamma_1), \ldots, \omega_{2\gamma}(\gamma_{m+k})\} \in H^1(\bar{\Gamma}, \rho'),$$

where $\rho'(\gamma_k) = 1$, $s = m + 1, \ldots, m + k$ and $\rho' = \rho$ on $\Gamma'_\mu \cong \bar{\Gamma}$. Since all $\omega_{2\alpha}(\gamma_s)$, for $s = m + 1, \ldots, m + k$, vanish, $[\omega]$ is expressed in terms of only $\omega_{2\alpha}(A), \omega_{2\beta}(B), \omega_{2\gamma}(\gamma_1), \ldots, \omega_{2\gamma}(\gamma_{m-1})$, satisfying (1), while for $\rho \neq 1$ we have $\omega_{2\alpha}(A) = 0$ for $\rho(A) \neq 1$, and $\omega_{2\beta}(B) = 0$ for $\rho(B) \neq 1$. Hence, the mapping $\Omega_{2,\rho}(F'_\mu) \ni \omega \mapsto [\omega] \in H^1(\Gamma'_\mu, \rho)$ is well-defined.

If the class of periods $[\omega] = 0$ in $H^1(\Gamma'_\mu, \rho)$ for $\omega \in \Omega_{2,\rho}(F'_\mu)$, then the differential $\omega$ is multiplicatively exact for $\rho$ on $F'_\mu$, and so $\omega \in \Omega_{e,\rho}(F'_\mu)$. If $\omega \in \Omega_{e,\rho}(F'_\mu)$, then, as above, $\omega_{2\alpha}(\gamma_s) = 0$ for $s = m + 1, \ldots, m + k$, where $\gamma_s$ is a loop enclosing only the pole $Q_s$ of $\omega$. By assumption, $\omega = df$, where $f$ is a multiplicative meromorphic function on $F'_\mu$, and so $\omega$ is well-defined in the sense of Gunning on $\omega$.

Thus, for every $\rho \neq 1$ the period mapping from $\Omega_{2,\rho}(F'_\mu)/\Omega_{e,\rho}(F'_\mu)$ into $H^1(\Gamma'_\mu, \rho)$ determined by the rule $\omega + \Omega_{e,\rho}(F'_\mu) \mapsto [\omega + \Omega_{e,\rho}(F'_\mu)] = [\omega]$ is well-defined, bijective, and linear. Consequently, $\dim_{\mathbb{C}} \Omega_{2,\rho}(F'_\mu)/\Omega_{e,\rho}(F'_\mu) \leq m$ for every $\rho \neq 1$.

**Theorem 3.1.** The vector bundle $E_1 = \bigcup \Omega_{2,\rho}(F'_\mu)/\Omega_{e,\rho}(F'_\mu)$ is holomorphic of rank $m$ over the base $T_{1,m} \times (L_1 \setminus \{1\})$ for $m \geq 2$. Furthermore, the tuples

$$f_0 \tau_{\tilde{P}_1}^{(2)}, f_0 \tau_{\tilde{P}_2} p_1, \ldots, f_0 \tau_{\tilde{P}_m} p_1,$$

(2)

of cosets of Prym differentials constitute bases of locally holomorphic sections of this bundle, where $f_0$ is a unitary function on $F'_\mu$ for $\rho$, $r_\rho(\tilde{P}_1^{-1}) = 1$ on $F'_\mu$ and point $\tilde{P}_1 \in F'_\mu$.

**Proof.** This bundle is well-defined over this base by Lemma 1.3. Let us establish the reverse inequality $\dim_{\mathbb{C}} \Omega_{2,\rho}(F'_\mu)/\Omega_{e,\rho}(F'_\mu) \geq m$ and construct a basis for this quotient space.

Verify that for $\rho \neq 1$, $\rho(A) \neq 1$, the differentials in the tuples (2) represent cosets in our quotient space which are linearly independent over $\mathbb{C}$. For $\rho_0 \neq 1$ on $\pi_1(F'_\mu)$ there exists $A \in \Gamma'_\mu$, satisfying $\rho_0(A) = \exp 2\pi i c \neq 1$. Thus, $c \neq 0$ for every $\rho$ in a sufficiently small neighborhood $U(\rho_0) \subset L_1 \setminus \{1\}$ and every $[\mu] \in U(\mu_0)$. Since $d_0 = 2\pi i c f_0 \zeta$ on $F'_\mu$, we can express $f_0 \zeta$ linearly via $d_0$. Consequently, instead of the differential $f_0 \zeta$ we can take $d_0$, which represents the zero coset. Suppose that there exists a linear combination with nonzero coefficients

$$c_1 f_0 \tau_{\tilde{P}_1}^{(2)} + \tilde{c}_1 f_0 \tau_{\tilde{P}_2} p_1 + \ldots + \tilde{c}_{m-1} f_0 \tau_{\tilde{P}_m} p_1 = d_f,$$

where $f$ is multiplicative function for an unessential character $\rho$ on $F'_\mu$ with $\rho_0(A) \neq 1$.

Go around the point $P_2$ along a small loop $\gamma_2$, starting from $\tilde{P}_2,0$ on $F'_\mu$. Then the expression on the left-hand side has the residue $\tilde{c}_1 f_0(\tilde{P}_2,0) \rho(\gamma_2)$, while this residue on the right-hand side vanishes. But $f_0(\tilde{P}_2,0) \neq 0$, $\rho(\gamma_2) = 1$, so $\tilde{c}_1 = 0$. In the same fashion we calculate the residues along small loops enclosing the points $P_3, \ldots, P_m$ and obtain $\tilde{c}_2 = \cdots = \tilde{c}_{m-1} = 0$. Then we are left with the sum $c_1 f_0(\tilde{P}_1) = d_f$.

Consider the coefficient $c_1$.

1) If $d_f$ has removable singularities at all punctures, then this equality on $F'_\mu$ implies that there exists a meromorphic multiplicative function on $F'_\mu$ with simple pole at $\tilde{P}_1$. But this is impossible by the choice of this point and the condition $r_\rho(\tilde{P}_1^{-1}) = 1$.
2) If the continuation of $df$ to $F_\mu$ has at least one pole or essential singularity at the punctures, then for the combination on the left-hand side this point (puncture) is not singular, while for $df$ it is singular. This is a contradiction. Therefore, $c_1 = 0$.

Thus, the differentials in the tuple (2) represent cosets in our quotient space which are linearly independent over $C$.

The case $\rho_0(B) \neq 1$ can be proved analogously. The proof of Theorem 3.1 is complete. □

Denote by $\Omega_\rho(\{Q_1, ... , Q_s\}; F_\mu')$ the space of the differentials for $\rho$, which are multiples of the divisor $\frac{1}{Q_1} + ... + \frac{1}{Q_s}$ on $F_\mu'$, and by $\Omega_{\text{hol}, \rho}(1; F_\mu')$, the subspace of the holomorphic multiplicatively exact differentials for $\rho$ on $F_\mu'$.

**Theorem 3.2.** The vector bundle $E_2 = \bigcup_{[\mu]} \Omega_\rho(\{Q_1, ... , Q_s\}; F_\mu') / \Omega_{\text{hol}, \rho}(1; F_\mu')$ is holomorphic of rank $m + s$ with the base $T_{1,m} \times \{\Lambda_1 \setminus \{1\}\}$ for $m \geq 2, s \geq 1$. Furthermore, the tuple

$$f_0 \tau_{P_1}, f_0 \tau_{P_2}, ... , f_0 \tau_{P_m P_1}, f_0 \tau_{Q_1}, ... , f_0 \tau_{Q_s},$$

(3)

of cosets of differentials constitutes a basis for locally holomorphic sections of this bundle, where $Q_1, ... , Q_s$ are distinct points on $F_\mu'$, depending holomorphically on $[\mu]$.

**Proof.** Consider the period mapping $\Omega_\rho(\{Q_1, ... , Q_s\}; F_\mu') \ni \omega \rightarrow [\omega] \in H^1(\Gamma''_\rho, \rho)$. The class of $[\omega]$ is determined by the tuple of classical periods $(\omega(A) = 0, \omega(B), \omega(\gamma_1), ... , \omega(\gamma_m - 1))$. Here the period $\omega(\gamma)$ is expressed via the remaining $m + s$ of periods, $F_\mu'' = F_\mu'' \{Q_1, ... , Q_s\} = F_\mu'' \{P_1, ... , P_m\} \cup \{Q_1, ... , Q_s\}$, and $F_\mu'' = U/\Gamma''_\rho$.

If $\Omega(\{Q_1, ... , Q_s\}; F_\mu') \ni \omega \rightarrow [\omega] = 0$ in $H^1(\Gamma''_\rho, \rho)$, then the differential $\omega$ is multiplicatively exact on $F_\mu'$. The points $Q_1, ... , Q_s$ are removable singularities for $\omega$ since $2\pi i (\text{res}_Q \omega) = \int_{\gamma_j} \omega = 0, \ n = 1, ... , s$. Thus, $\omega \in \Omega_{\text{hol}, \rho}(1; F_\mu')$. Consequently, the period mapping is well-defined, bijective, and takes $\Omega_\rho(\{Q_1, ... , Q_s\}; F_\mu') / \Omega_{\text{hol}, \rho}(1; F_\mu')$ linearly into $H^1(\Gamma''_\rho, \rho)$. Thus, $\dim \Omega_\rho(\{Q_1, ... , Q_s\}; F_\mu') / \Omega_{\text{hol}, \rho}(1; F_\mu') \leq m + s$.

Let us establish the reverse inequality for the dimension and construct a basis. The tuple of cosets of differentials in (3) is linearly independent over $C$. Indeed, if

$$C_1 f_0 \tau_{P_1} + \cdots + C_{m-1} f_0 \tau_{P_{m-1}} + c_1 f_0 \tau_{Q_1} + \cdots + c_s f_0 \tau_{Q_s} = df,$$

then $C_1 = \cdots = C_{m-1} = c_1 = \cdots = c_s = 0$ since $f$ is a multiplicative meromorphic function for $\rho$ on $F_\mu'$ and its residues at the points $P_2, ... , Q_s$ vanish.

This yields the equality $C_1 f_0 \tau_{P_1} = df$. If the continuation $f$ has in the punctures a unique pole $P_1$, then $(f) \geq 1 \geq \frac{1}{P_1}$. But this is impossible because of the condition $r_1(\frac{1}{P_1}) = 1$, since we have the inequality $(f) \geq 1 \geq \frac{1}{P_1}$. This is a contradiction. Hence, the dimension of the quotient space is at least $m + s$ and we have constructed a basis. The proof of Theorem 3.2 is complete. □

By Grauert’s theorem, since the base is simply connected, we obtain

**Corollary 3.1.** The holomorphic vector bundle (with fibers consisting of the first holomorphic de Rham cohomology groups for $\rho$ on $F_\mu'$) $E_2 = \bigcup_{[\mu], \rho \neq 1} H^1_{\text{hol}, \rho}(F_\mu') = \bigcup_{[\mu]} \Omega_\rho(1; F_\mu') / \Omega_{\text{hol}, \rho}(1; F_\mu')$ is analytically equivalent to the trivial rank $m$ vector bundle with the base $T_{1,m} \times \{\Lambda_1 \setminus \{1\}\}$ for $m \geq 2$.

Define the period mapping $\chi$ from $\Omega_\rho(1; F_\mu')$ onto $H^1(\Gamma', \rho)$, associating to $\omega$ its class of periods $[\omega]$, which is determined by the tuple of classical periods $\left(\int_a \omega, \int_b \omega, \int_{\gamma_1} \omega, ..., \int_{\gamma_m} \omega\right)$. Choose a representative for $[\omega]$ satisfying $\int_a \omega = \omega(A) = 0$. 

– 169 –
Corollary 3.2. On every surface $F'_\mu$ of type $(1, m)$, $m \geq 2$, given an unessential character $\rho$, we have an isomorphism $\Omega_{c, \rho}(1; F'_\mu) \cong \text{Ker} \chi \oplus H^1_{\text{hol}, \rho}(F'_\mu)$, where $\text{Ker} \chi = \Omega_{c, \rho}(1; F'_\mu)$ is an infinite dimensional vector space and $\dim_{\mathbb{C}} H^1_{\text{hol}, \rho}(F'_\mu) = m$.

4. Prym differentials for an essential character

Lemma 4.1. On a surface $F'_\mu$ of type $(1, m)$, $m \geq 1$, given an essential character $\rho$, there exists a $(\rho, 1)$-differential $\tau = \tau_{\rho; Q^2P_1}$, where $Q \in F'_\mu$ such that $\tau = \frac{R_1 \ldots R_n}{Q^2P_1P_2^2 \ldots P_m^m}$ on $F'_\mu$, where $k_j \in \mathbb{N}, j = 2, \ldots, m$, and $R_\alpha \neq P_1, Q_\alpha, k = 1, \ldots, N, N = 3 + k_2 + \cdots + k_m$, depending locally holomorphically on $[\mu]$ and $\rho$.

Proof. Proceed as in Section 3.

Theorem 4.1. The vector bundle $E_3 = \bigcup \Omega_{c, \rho}(F'_\mu)/\Omega_{c, \rho}(F'_\mu)$ is holomorphic of rank $m$ with the base $T_{1,m} \times \text{Hom}(\Gamma', \mathbb{C}^*) \setminus L_1$ for $m \geq 2$. Furthermore, the tuples : either

$$\tau_{\rho; P_2P_1, \ldots, P_mP_1, \tau_{\rho; Q^2P_1}} (4)$$

or

$$\tau_{\rho; P_2P_1, \ldots, P_mP_1} (5)$$

of cosets of differentials constitute a basis for locally holomorphic sections of this bundle, where $Q \in F'_\mu$.

Proof. Take an essential character $\rho$ on $F'_\mu$. Define a mapping $\Phi$ from $\Omega_{2, \rho}(F'_\mu)$ into $H^1(\Gamma'_\mu, \rho)$, by associating to a differential $\omega$ its class of periods $[\omega] \in H^1(\Gamma'_\mu, \rho)$.

If $\omega \in \Omega_{2, \rho}(F'_\mu)$ satisfies $[\omega] = 0$ in $H^1(\Gamma'_\mu, \rho)$, then $\omega$ is multiplicative exact for $\rho$ on $F'_\mu$, and hence $\omega \in \Omega_{c, \rho}(F'_\mu)$. It is clear also that every differential $\omega$ in $\Omega_{c, \rho}(F'_\mu)$ has the vanishing class of periods. Therefore, the kernel of $\Phi$ coincides with $\Omega_{c, \rho}(F'_\mu)$. Consequently, this mapping is well-defined on the quotient space $\Omega_{2, \rho}(F'_\mu)/\Omega_{c, \rho}(F'_\mu)$. Furthermore, $\Phi$ is bijective and linear. This implies that $\dim_{\mathbb{C}} \Omega_{2, \rho}(F'_\mu)/\Omega_{c, \rho}(F'_\mu) \leq m$.

Let us establish the reverse inequality for the dimension and construct two forms of basis for our quotient space.

By Theorem 2.2, there exists a tuple $\tau_{\rho; P_2P_1, \ldots, P_mP_1}$ of elementary Prym differentials of third kind with simple poles at the points $P_j$ and $P_1$, $j = 2, \ldots, m$, on $F'_\mu$ respectively.

Suppose that the tuple (4) represents linearly dependent cosets in our quotient space for the essential character $\rho$; therefore, there exists a nontrivial linear combination with nonzero coefficients:

$$\tilde{c}_1 \tau_{\rho; P_2P_1} + \cdots + \tilde{c}_{m-1} \tau_{\rho; P_mP_1} + \tilde{c}_m \tau_{\rho; Q^2P_1} = df,$$

for fixed $Q \in F'_\mu$, where $f$ is a multiplicative function on $F'_\mu$, (possibly, with poles of arbitrary orders and essential singularities in punctures for the branches of this function on $F'_\mu$).

Consider the coefficients $\tilde{c}_j, j = 1, \ldots, m-1$. For $j = 2, \ldots, m$, take a loop $\gamma_j$ enclosing only the point $P_j$. Then the classical period $\int_{\gamma_j} df = c\sigma(\gamma_j)$ and, choosing instead of $f$ the function $f - c$, we obtain $\int_{\gamma_j} d(f - c) = 0$. Consequently, all coefficients $\tilde{c}_1 = \cdots = \tilde{c}_{m-1} = 0$.

What’s left to prove is the equality $\tilde{c}_m \tau_{\rho; Q^2P_1} = df$. Go along $\gamma_1$ around the point $P_1$ and calculate residue at point, we obtain that $\tilde{c}_m = 0$.

We can prove the same statement for tuple (5) in same fashion.

The theorem 4.1 is proved. \(\square\)
Theorem 4.2. The vector bundle $E_4 = \bigcup \Omega_{\rho}((1; F_{1}^{\alpha})/\Omega_{c,\rho}(1, F_{1}^{\alpha}))$ is holomorphic of rank $m+s$ with the base $T_{1,m} \times Hom(1, C^{*}) \setminus L_{1}$ for distinct points $Q_{1},\ldots,Q_{s}$, $s \geq 1$, on the surface $F_{1}^{\alpha}$ of type $(1,m)$, $m \geq 2$. Furthermore, the tuple : either

$$
\tau_{\rho;P_{1},\ldots,\tau_{\rho;P_{m}}}, \tau_{\rho;Q_{1},\ldots,\tau_{\rho;Q_{s}}},
$$

(6)
of cosets of Prym differentials constitutes a basis for locally holomorphic sections of this bundle.

Remark 1. The vector bundles $E_1$ and $E_3$ are analytically equivalent to the Gunning cohomological bundle $G'$ over their respective bases.

Remark 2. Theorems 3.2 and 4.2, taking into account theorems 2.1 and 2.2, can be generalized for vector bundles with fibers $\Omega_{\rho}((1; F_{1}^{\alpha})/\Omega_{c,\rho}(1, F_{1}^{\alpha}))$, over the products $T_{1,m} \times Hom(1, C^{*}) \setminus L_{1}$ and $T_{1,m} \times L_{1} \setminus 1$ for $s \geq 1$, $\alpha_{1},\ldots,\alpha_{s} \in N$, $q > 1$.
