In this note, we obtain exact values of the partition function of Kostant for the simple Lie algebra $\mathfrak{sp}_4(\mathbb{C})$. Using the values of the partition function, we can find the weight multiplicities of irreducible representations of $\mathfrak{sp}_4(\mathbb{C})$ by a simple computation.

Keywords: symplectic Lie algebra, Kostant partition function, Weyl group, weight multiplicity.

Introduction

Let $L$ be a finite dimensional complex semi-simple Lie algebra with a Cartan subalgebra $H$ and root system $\Phi$ and suppose $\Phi^+$ denotes the set of positive roots. Recall that the Weyl vector is defined by

$$\rho = \sum_{\alpha \in \Phi^+} \alpha.$$

Suppose $\lambda$ is an integral dominant weight of $L$ and $V(\lambda)$ is the corresponding irreducible $L$-module. For any other integral dominant weight $\mu$, we define the multiplicity of $\mu$ in $\lambda$ to be the dimension of

$$V(\lambda)_\mu = \{ v \in V(\lambda) : \forall h \in H \quad h.v = \mu(h)v \}.$$

There exists a compact formula for computing weight multiplicities, known as Kostant’s multiplicity formula. It can be stated as follows,

$$\dim V(\lambda)_\mu = \sum_{\omega \in \mathcal{W}} \epsilon(\omega) \mathfrak{P}(\omega(\lambda + \rho) - (\mu + \rho)).$$

Here $\mathcal{W}$ is the Weyl group of $L$, $\epsilon(\omega)$ is the sign of $\omega$, and $\mathfrak{P}$ is the Kostant partition function. By definition, for any weight $\gamma$, $\mathfrak{P}(\gamma)$ is the number of ways to write $\gamma$ as a linear combination of positive roots with non-negative coefficients, (see [1] for details). Although the Kostant partition function is a well-known classical notion in Lie algebra, an explicit expressions for it, might not be easy to find in the literature. In this note, we give an explicit formula for the values of the partition function, in the case $L = \mathfrak{sp}_4(\mathbb{C})$.

1. Generalities

In this elementary section, we give a review of theories concerning the Lie algebra \( \mathfrak{sp}_4(\mathbb{C}) \). We also fix a set of notations we will use in the next sections.

The symplectic Lie algebra, \( \mathfrak{sp}_4(\mathbb{C}) \), is a 10-dimensional simple Lie algebra defined by

\[
\mathfrak{sp}_4(\mathbb{C}) = \{ x \in Mat_4(\mathbb{C}) : sx = -x^T s \},
\]

where

\[
s = \begin{pmatrix} 0 & I_2 \\ -I_2 & 0 \end{pmatrix}
\]

A Cartan subalgebra for \( \mathfrak{sp}_4(\mathbb{C}) \) is \( H \) which consists of diagonal matrices

\[
h = \text{diag}(a_1, a_2, -a_1, -a_2),
\]

where \( a_1, a_2 \in \mathbb{C} \). For \( i = 1, 2 \), define a functional \( \mu_i : H \to \mathbb{C} \) by \( \mu_i(h) = a_i \). So the set

\[
\Phi = \{ \pm \mu_i \pm \mu_j : 1 \leq i, j \leq 2\} - \{0\}
\]

is a root system for \( \mathfrak{sp}_4(\mathbb{C}) \). Also, the set

\[
\Pi = \{R_1 = \mu_1 - \mu_2, R_2 = 2\mu_2\}
\]

is a basis for \( \Phi \). Finally

\[
\lambda_1 = \mu_1, \quad \lambda_2 = \mu_1 + \mu_2
\]

are fundamental weights of \( \mathfrak{sp}_4(\mathbb{C}) \). Note that, we also have the following simple relations;

\[
\begin{align*}
\mu_1 &= \lambda_1 \\
\mu_2 &= -\lambda_1 + \lambda_2 \\
R_1 &= 2\lambda_1 - \lambda_2 \\
R_2 &= -2\lambda_1 + 2\lambda_2 \\
\lambda_1 &= R_1 + \frac{1}{2}R_2 \\
\lambda_2 &= R_1 + R_2.
\end{align*}
\]

We denote the Weyl group by \( W \). It is generated by the reflection \( \sigma_\alpha, \alpha \in \Pi \), where

\[
\sigma_\alpha(\beta) = \beta - \frac{2(\beta, \alpha)}{(\alpha, \alpha)} \alpha,
\]

for \( \beta \in \Phi \). Let \( \sigma_1 = \sigma_{R_1} \) and \( \sigma_2 = \sigma_{R_2} \). In the following table, we give the elements of \( W \) by their actions on the elements \( \mu_1 \) and \( \mu_2 \), their expressions as products of \( \sigma_1 \) and \( \sigma_2 \), and their sign, \( \epsilon(\omega) \).

</table>
Let $\lambda = a \lambda_1 + b \lambda_2$ be an integral dominant weight of $\mathfrak{sp}_4(\mathbb{C})$. We denote the corresponding $\mathfrak{sp}_4(\mathbb{C})$-module by $V(\lambda)$. Using Weyl’s dimension formula, (see [1], page 267), we have
\[
\dim V(\lambda) = \frac{1}{6}(a + 1)(b + 1)(a + b + 2)(a + 2b + 3).
\]
Equivalently, if $\lambda = p \mu_1 + q \mu_2$, we have
\[
\dim V(\lambda) = \frac{1}{6}(p + 2)(q + 1)(p + q + 3)(p - q + 1).
\]

Now, we are going to compute the weight multiplicities for $\mathfrak{sp}_4(\mathbb{C})$. These are very important for decomposition of a $\mathfrak{sp}_4(\mathbb{C})$-module into the direct sum of irreducible constituents. For this purpose, we use the Kostant multiplicity formula;
\[
\dim V(\lambda)_{\mu} = \sum_{\omega \in \Omega} \epsilon(\omega) \Psi(\omega(\lambda + \rho) - (\mu + \rho)),
\]
where $\rho = \lambda_1 + \lambda_2$ and $\Psi$ is the partition function, i.e. $\Psi(\mu)$ is the number of ways to write $\mu$ as a linear combination of positive roots with non-negative integer coefficients.

Suppose $\lambda = p \mu_1 + q \mu_2$ and $\mu = r \mu_1 + s \mu_2$. Since we have $\rho = 2 \mu_1 + 2 \mu_2$, so using the above table,
\[
\dim V(\lambda)_{\mu} = \sum_{i=1}^{8} \epsilon(\omega_i) \Psi(\omega_i(\lambda + \rho) - (\mu + \rho))
\]
\[
= \sum_{i=1}^{8} \epsilon(\omega_i) \Psi((p + 2)\mu_1 + (q + 1)\mu_2)
\]
\[
= \sum_{i=1}^{8} \epsilon(\omega_i) \Psi((p + 2)\mu_1 + (q + 1)\mu_2)
\]
\[
= \Psi((p - r)\mu_1 + (q - s)\mu_2)
\]
\[
- \Psi((q - r - 1)\mu_1 + (p - s + 1)\mu_2)
\]
\[
- \Psi((p - r)\mu_1 - (q + s + 2)\mu_2)
\]
\[
+ \Psi((q - r - 1)\mu_1 + (p + s + 3)\mu_2).
\]

It is enough to know the values of $\Psi(\gamma)$ for the following cases,

**Case 1:** $\gamma = i \mu_1 + j \mu_2$ such that $i, j \geq 0$ and $i + j$ is even.

**Case 2:** $\gamma = i \mu_1 - j \mu_2$ such that $i \geq j > 0$ and $i + j$ is even.

## 2. Values of the Partition Function

In what follows, we obtain the exact values of $\Psi(\gamma)$. We know that the positive roots of $\mathfrak{sp}_4(\mathbb{C})$ are $\beta_1 = \mu_1 - \mu_2$, $\beta_2 = \mu_1 + \mu_2$, $\beta_3 = 2 \mu_1$, $\beta_4 = 2 \mu_2$.

Now, we have
\[
\Psi(\gamma) = |\{(r_1, r_2, r_3, r_4) : r_i \in \mathbb{Z}, r_i \geq 0, \gamma = \sum_{i=1}^{4} r_i \beta_i\}|.
\]

Let $\gamma = i \mu_1 + j \mu_2$. If it is possible to write $\gamma$ as non-negative integer linear combination of $\beta$s, then we have
\[
i \mu_1 + j \mu_2 = r_1 \beta_1 + r_2 \beta_2 + r_3 \beta_3 + r_4 \beta_4
\]
\[
= (r_1 + r_2 + 2r_3)\mu_1 + (-r_1 + r_2 + 2r_4)\mu_2,
\]
so we must have

\[ i = r_1 + r_2 + 2r_3, \quad j = -r_1 + r_2 + 2r_4. \]

Hence we obtain the following results;

1. If \( i + j \) is odd, then \( \Psi(\gamma) = 0 \).
2. If \( i < 0 \), then \( \Psi(\gamma) = 0 \).
3. If \(-j > i \geq 0\), then \( \Psi(\gamma) = 0 \).

It is enough to know the values of \( \Psi(\mu) \) for the following cases,

\textbf{Case 1:} \( \gamma = i\mu_1 + j\mu_2 \) such that \( i, j \geq 0 \) and \( i + j \) is even.

\textbf{Case 2:} \( \gamma = i\mu_1 - j\mu_2 \) such that \( i \geq j > 0 \) and \( i + j \) is even.

Let \( \gamma = i\mu_1 + j\mu_2 \) such that \( i, j \geq 0 \) and \( i + j \) is even. Then \( \Psi(\gamma) \) is the number of non-negative integer solutions of

\[ r_1 + r_2 + 2r_3 = i \]
\[ -r_1 + r_2 + 2r_4 = j \]

Adding up two equations, we obtain

\[ r_2 + r_3 + r_4 = \frac{i + j}{2}. \]

Also, subtraction gives

\[ r_1 = \frac{i - j}{2} + r_4 - r_3. \]

So, \( \Psi(\gamma) \) is the number of integer solutions of the following system;

\[ x + y + z = \frac{i + j}{2} \]
\[ x + 2y \leq i \]
\[ x + 2z \geq j \]
\[ x, y, z \geq 0 \]

We consider two cases: \( j < i \) and \( i \leq j \). In the first case, we see that \( \Psi(\gamma) \) is the number of solutions of the system;

\[ x + y \leq \frac{i + j}{2} \]
\[ x + 2y \leq i \]
\[ x, y \geq 0 \]

\textbf{Lemma 2.1.} The number of integer solutions of the system

\[ x + y \leq k \]
\[ x, y \geq 0 \]

is equal to

\[ n = \frac{(k + 1)(k + 2)}{2}. \]
Proof. For $0 \leq l \leq k$, let

$$A_l = \{(x, l) : x \geq 0, \ x + l \leq k\}.$$  

So, we have $|A_l| = k - l + 1$. Thus

$$n = \sum_{l=1}^{k} |A_l| = \frac{(k+1)(k+2)}{2}.$$  

Corollary 2.1. The number of the integer solutions of the system

\[
\begin{align*}
x + y & \leq k \\
0 \leq y & \leq l \\
x & \geq 0
\end{align*}
\]

is equal to

$$\frac{(l+1)(2k+2-l)}{2}.$$  

Lemma 2.2. The number of the integer solutions of the system

\[
\begin{align*}
x + 2y & \leq k \\
x, y & \geq 0
\end{align*}
\]

is equal to

$$n = \frac{(k+2)^2}{4},$$

if $k$ is even, otherwise

$$n = \frac{(k+1)(k+3)}{4}.$$  

Proof. For $0 \leq l \leq k$, suppose

$$A_l = \{(x, l) : x \geq 0, x + 2l \leq k\}.$$  

Then, we have

$$|A_l| = k - 2l + 1,$$

and hence, for even $k$

$$n = 1 + 3 + \cdots + (k+1) = \frac{(k+2)^2}{4},$$

and for odd $k$, we have

$$n = 2 + 4 + \cdots + (k+1) = \frac{(k+1)(k+3)}{4}.$$  

Corollary 2.2. Suppose $n$ is the number of integer solutions of the system

\[
\begin{align*}
x + 2y & \leq k \\
0 \leq l & \leq y \\
x & \geq 0
\end{align*}
\]
If $k$ is even, then we have

$$n = \frac{(k - 2l + 2)^2}{4},$$

and otherwise

$$n = \frac{(k - 2l + 1)(k - 2l + 3)}{4}.$$

We return to the system

$$\begin{align*}
x + y &\leq \frac{i + j}{2} \\
x + 2y &\leq i \\
x, y &\geq 0
\end{align*}$$

where $j \leq i$ and $i + j$ is even. One can split this system into two complementary systems as follows,

$$\begin{align*}
x + y &\leq \frac{i + j}{2} \\
0 &\leq y \leq \frac{i - j}{2} \\
x &\geq 0
\end{align*}$$

and

$$\begin{align*}
x + 2y &\leq i \\
y &\geq \frac{i - j + 1}{2} \\
x &\geq 0.
\end{align*}$$

So, using Lemmas 3-2 and 3-4, we obtain

**Corollary 2.3.** Let $\gamma = i\mu_1 + j\mu_2$ such that $0 \leq j < i$ and $i + j$ is even. If $j$ is even, then

$$\mathcal{P}(\gamma) = \frac{(i - j + 2)(i + 3j + 4) + 2j^2}{8},$$

and if $j$ is odd, then we have

$$\mathcal{P}(\gamma) = \frac{(i - j + 2)(i + 3j + 4) + 2(j^2 - 1)}{8}.$$

Now, suppose we have $i \leq j$. It is easy to see that in this case, $\mathcal{P}(\gamma)$ is the number of solutions of the system

$$\begin{align*}
x + 2y &\leq i \\
x, y &\geq 0.
\end{align*}$$

Hence, we obtain:

**Corollary 2.4.** Let $\gamma = i\mu_1 + j\mu_2$ such that $0 \leq i \leq j$ and $i + j$ is even. If $i$ is even, then

$$\mathcal{P}(\gamma) = \frac{(i + 2)^2}{4},$$

while in the other case

$$\mathcal{P}(\gamma) = \frac{(i + 1)(i + 3)}{4}.$$
Finally, we consider the case \( \gamma = \imath \mu_1 - \jmath \mu_2 \), with \( i + j \) even and \( 0 < j \leq i \). Again, \( \Psi(\gamma) \) is the number of non-negative integer solutions of the system

\[
\begin{align*}
  r_1 + r_2 + 2r_3 &= i \\
  -r_1 + r_2 + 2r_4 &= -j
\end{align*}
\]

Adding up two equations, we obtain

\[ r_2 + r_3 + r_4 = \frac{i - j}{2}. \]

Also, subtraction gives

\[ r_1 = \frac{i + j}{2} + r_4 - r_3. \]

We see that if \((r_2, r_3, r_4)\) satisfies

\[
\begin{align*}
  r_2 + r_3 + r_4 &= \frac{i - j}{2} \\
  r_2 &\geq 0 \\
  r_3 &\geq 0 \\
  r_4 &\geq 0
\end{align*}
\]

then \((r_1, r_2, r_3, r_4)\) is a non-negative integral solution to the above system, and moreover every solution can be obtain by this method. Hence the required number is just the number of solutions of the simple system

\[
\begin{align*}
  x + y &\leq \frac{i - j}{2} \\
  x, y &\geq 0
\end{align*}
\]

and so we have

**Corollary 2.5.** Suppose \( \gamma = \imath \mu_1 - \jmath \mu_2 \), with \( i + j \) even and \( 0 < j \leq i \). Then we have

\[
\Psi(\gamma) = \frac{(i - j + 2)(i - j + 4)}{8}.
\]
