We consider the Cauchy problem for a loaded partial differential equation arising in coefficient inverse problem. The convergence of Tonelli’s and weak approximation methods for this problem is previously proved. In the article we will prove linear rate of convergence of given methods.

Keywords: differential equation, inverse problem, Cauchy problem, Tonelli’s method, weak approximation method, convergence.

1. Auxiliary symbols and theorems

We will use the following notation.

\( \Omega \) is bounded domain in the \( E^n \) space. \( x = (x_1, \ldots, x_n) \) is a point in \( E^n \). \( \partial \Omega \) is the boundary of \( \Omega \). \( Q_T \) is the cylindrical domain \( (0, T) \times \Omega \).

\( C^k(\Omega) \) (\( C^k(\Omega) \)) is the set of all \( k \) times continuously differentiable functions of \( \tilde{\Omega} \) (\( \Omega \)), having bounded derivatives up to \( k \)-th order.

\( \Pi_{[0,T]} = \{(t,x)|t \in [0,T], x \in E^n\} \).

\( \Pi_{[0,T]}^{M} = \{(t,x)|t \in [0,T], x \in E^n, |x| \leq M, M - \text{const}\} \).

\( C^{k,m}(0,T], \Omega) \) \( (C^{k,m}(\Pi_{[0,T]}) \) is the set of all functions of \( n+1 \) variables \( (t,x_1, \ldots, x_n) \) in \( \Pi_{[0,T]} \), which are \( k \) times continuously differentiable with respect to \( t \) and \( m \) times continuously differentiable with respect to spartial variables. All the derivatives listed above are bounded in \( \Pi_{[0,T]} \).

\( \tau \) is a real-valued parameter, \( \tau \in [0,\tau_0] \), \( \tau_0 > 0 \).

\( A, B, C_i, i \in \mathbb{N} \), are nonnegative constants depending on the initial data of problems being investigated but do not depending on \( \tau \).

**Mean value theorem for Definite integral.** Let \( f(x) \) be a continuous function defined for \( x \in [a,b] \). Then

\[
\int_a^b f(x)dx = f(\xi)(b-a), \quad a \leq \xi \leq b.
\]
2. The Cauchy problem

We consider the inverse problem with unknown coefficient \( \mu(t) \):

\[
\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + \mu(t)f(t, x),
\]

\( u(0, x) = u_0(x), \)

\( u(t, 0) = \varphi(t), \)

for \((t, x) \in \Pi_{[0,T]}, n = 1\).

We consider

\( u_0(0) = \varphi(0), \)

(4)

\( u_0(x) \) and \( f(t, x) \) are bounded and arbitrary smooth functions. By substitution \( x = 0 \) into (1) and using (3) we find unknown \( \mu(t) \)

\[
\mu(t) = \frac{\varphi'(t) - u_{xx}(t, 0)}{f(t, 0)}.
\]

Using (5) we reduce inverse problem (1)–(3) to the Cauchy problem for a loaded equation

\[
\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + \phi(t, x)(\varphi'(t) - u_{xx}(t, 0)),
\]

\( u(0, x) = u_0(x), \)

(7)

where \( \phi(t, x) = f(t, x)/f(t, 0) \).

3. Lemma 1

Consider the one-dimensional problem

\[
\frac{\partial z^\tau}{\partial t} = \frac{\partial^2 z^\tau}{\partial x^2} - \phi(t, x)z_{xx}^\tau(t, 0) + F_\tau(t, x), \quad \tau \in [0, \tau_0],
\]

\( z^\tau(t, x)|_{\tau \leq \xi \leq 0} = 0, \)

(9)

in domain \( \Pi_{[0,T]} \). If \( z^\tau(t, x) \in C^{1,4}(\Pi_{[0,T]}) \) is a solution to (8), (9), \( \phi(t, x) \in C^{0,2}(\Pi_{[0,T]}), \)

\( F_\tau(t, x) \in C^{0,2}(\Pi_{[0,T]}), \)

\( \left| \frac{\partial^k}{\partial x^k} F_\tau(t, x) \right| \leq A \tau, \quad 0 \leq k \leq \tau, \) then \( |z^\tau(t, x)| \leq B \tau, \) where \( A, B \) are constants not depending on \( \tau \).

Proof. Note that (8), (9) have a unique solution [2, p. 65]. By applying the maximum principle [3, p. 16] to (8), (9) in domain \( \Pi_{[0,t]}, 0 < t \leq T, \)

\[
|z^\tau(\eta, x)| \leq \sup_{E^1} |z^\tau(0, x)| + \eta \left( C_1 \sup_{\Pi_{[0,t]}} |z_{xx}^\tau(\theta, x)| + \sup_{\Pi_{[0,t]}} |F_\tau(\theta, x)| \right), \quad \eta \in [0, t].
\]

Here, \( C_1 \) is a constant limiting \( |\phi(t, x)| \). By applying \( \sup_{\Pi_{[0,t]}} \) to both sides of previous inequality,

\[
\sup_{\Pi_{[0,t]}} |z^\tau(\eta, x)| \leq \sup_{E^1} |z^\tau(0, x)| + C_2 t \left( \sup_{\Pi_{[0,t]}} |z_{xx}^\tau(\theta, x)| + \sup_{\Pi_{[0,t]}} |F_\tau(\theta, x)| \right),
\]

\( C_2 = \max(C_1, 1). \)
We differentiate (8), (9) two times with respect to $x$ and apply the maximum principle to the resulting equation,

$$
\sup_{\Pi_{[0,t]}} |z_{xx}^\tau(\eta, x)| \leq \sup_{E^1} |z_{xx}^\tau(0, x)| + C_4 t \left( \sup_{\Pi_{[0,t]}} |z_{xx}^\tau(\theta, x)| + \sup_{\Pi_{[0,t]}} \left| \frac{\partial^2}{\partial x^2} F^x(\theta, x) \right| \right), \quad (11)
$$

where $C_3 = \sup_{\Pi_{[0,t]}} |\phi_{xx}(t, x)|$. We denote $\gamma(t) = \sup_{\Pi_{[0,t]}} |z_{x}^\tau(\theta, x)| + \sup_{\Pi_{[0,t]}} |z_{xx}^\tau(\theta, x)|$ [2, p. 65]. Note, that

$$
\gamma(0) = \sup_{E^1} |z^\tau(0, x)| + \sup_{E^1} |z_{xx}^\tau(0, x)| = 0.
$$

By summing up (10) and (11),

$$
\gamma(t) \leq \gamma(0) + C_4 t \sup_{\Pi_{[0,t]}} |z_{xx}^\tau(\theta, x)| + C_5 \tau t \leq C_6 t \gamma(t) + C_6 \tau t,
$$

$$
C_4 = C_2 + C_3, \quad C_5 = 2C_4 A, \quad C_6 = \max(C_4, C_5).
$$

(12)

Let $t^* > 0$ be a constant such as $1 - C_6 t^* = \delta > 0$, $t^* K \geq T$, $K$ is integer. Note that $t^*$ and $\delta$ not depend on $\tau$. Thus,

$$
\gamma(t) \leq \delta^{-1} C_6 \tau t^*, \quad 0 \leq t \leq t^*.
$$

(13)

We consider (8), (9) in domain $\Pi_{[t^*, 2t^*]}$. From (13)

$$
\sup_{E^1} |z^\tau(t^*, x)| + \sup_{E^1} |z_{xx}^\tau(t^*, x)| \leq \delta^{-1} C_6 \tau t^*.
$$

Similarly to (10), (11), we prove

$$
\sup_{\Pi_{[t^*, t]}} |z^\tau(\eta, x)| \leq \sup_{E^1} |z^\tau(t^*, x)| + C_2 (t - t^*) \left( \sup_{\Pi_{[t^*, t]}} |z_{xx}^\tau(\theta, x)| + \sup_{\Pi_{[t^*, t]}} |F_x(\theta, x)| \right),
$$

$$
\sup_{\Pi_{[t^*, t]}} |z_{xx}^\tau(\eta, x)| \leq \sup_{E^1} |z_{xx}^\tau(t^*, x)| + C_5 (t - t^*) \left( \sup_{\Pi_{[t^*, t]}} |z_{xx}^\tau(\theta, x)| + \sup_{\Pi_{[t^*, t]}} \left| \frac{\partial^2}{\partial x^2} F^x(\theta, x) \right| \right),
$$

$$(1 - C_6 (t - t^*)) \gamma(t) \leq \delta^{-1} C_6 \tau t^* + C_6 \tau t^*,$$

and finally,

$$
\gamma(t) \leq \delta^{-1} \left( \delta^{-1} C_6 \tau t^* + C_6 \tau t^* \right), \quad 0 \leq t \leq 2t^*.
$$

By applying exact same reasoning in domain $\Pi_{[2t^*, 3t^*]}$, we prove

$$
\gamma(t) \leq \delta^{-1} \left( \delta^{-1} C_6 \tau t^* + C_6 \tau t^* \right) + C_6 \tau t^* = C_6 \tau t^* \sum_{i=1}^{3} \delta^{-i}, \quad 0 \leq t \leq 3t^*.
$$

Making $K$ steps, we prove

$$
\sup_{\Pi_{[0,T]}} |z(t, x)| \leq \gamma(T) = C_6 \tau t^* \sum_{i=1}^{K} \delta^{-i} = B \tau.
$$
4. Tonelli’s method

Let $\tau \in [0, \tau_0]$ be a constant such that $N\tau = T$, $N$ is integer. We make time shift by $\tau$ in trace of unknown function:

\[
\frac{\partial u^\tau}{\partial t} = \frac{\partial^2 u^\tau}{\partial x^2} + \phi(t, x)(\varphi'(t) - u_{xx}^\tau(t - \tau, 0)),
\]

\[
u^\tau(t, x)\big|_{-\tau \leq t \leq 0} = u_0(x).
\]

The method of solving problems like (6), (7) by approximation (14), (15) is called Tonelli’s method [1].

We consider initial data of the Cauchy problem (6), (7) to satisfy the following conditions:

\[
u_0(x) \in C^k(E^1), \quad f(t, x) \in C^{0,k}([0,T]), \quad k \geq 6, \quad \varphi(t) \in C^2([0,T]), \quad f(t, 0) \geq \delta > 0.
\]

By (16), the problem (14), (15) is a Cauchy problem for a heat equation with continuous and bounded coefficients, which have a solution $u^\tau$ for any $\tau \in [0, \tau_0]$.

**Remark.** The problem (14), (15) is a particular case of problem (4.1.8), (4.1.9) [2, p. 60] with $a(t) = 1$, $b(t) = c(t) = \gamma = 0$. Under Theorem 4.1.1 [2, p. 64], the solution $u^\tau(t, x)$ of problem (14), (15) converges to solution $u(t, x)$ of problem (6), (7) with $\tau \to 0$.

We prove inequalities (4.1.15) [2, p. 61] for $k$ from 1 to 6 and (4.1.16) [2, p. 61] for $k$ from 0 to 4 exactly same way as in proof of Theorem 4.1.1. Using Theorem 4.1.1,

\[
\frac{\partial}{\partial t} u^\tau(t, x) \leq C_7, \quad \frac{\partial^k}{\partial x^k} u^\tau(t, x) \leq C_8, \quad k = 0, \ldots, 6.
\]

\[
\frac{\partial^k}{\partial x^k} u^\tau(t, x) \leq C_9, \quad k = 0, \ldots, 4, \quad (t, x) \in P_i[0,T].
\]

Here and later, $C_i$ are constants (maybe different ones) depending on initial data of the problem (6), (7), but not depending on $\tau$.

We denote $z^\tau = u^\tau - u$. With substraction (6), (7) from (14), (15), function $z^\tau$ is a solution to

\[
\frac{\partial z^\tau}{\partial t} = \frac{\partial^2 z^\tau}{\partial x^2} + \phi(t, x)\tilde{F}_\tau(t),
\]

\[
z^\tau(0, x) = 0,
\]

where

\[
\tilde{F}_\tau(t) = \begin{cases}
    u_{xx}(t, 0) - u_0''(0), & t \leq \tau, \\
    u_{xx}(t, 0) - u_{xx}^\tau(t - \tau, 0), & t > \tau.
\end{cases}
\]

We add and substract $u_{xx}^\tau(t, 0)$ to $\tilde{F}_\tau$:

\[
\tilde{F}_\tau(t) = \begin{cases}
    [u_{xx}(t, 0) - u_{xx}^\tau(t, 0)] + [u_{xx}^\tau(t, 0) - u_0''(0)], & t \leq \tau, \\
    [u_{xx}(t, 0) - u_{xx}^\tau(t, 0)] + [u_{xx}^\tau(t, 0) - u_{xx}^\tau(t - \tau, 0)], & t > \tau.
\end{cases}
\]

Thus, function $z$ is a solution to

\[
\frac{\partial z^\tau}{\partial t} = \frac{\partial^2 z^\tau}{\partial x^2} - \phi(t, x)z_{xx}^\tau(0, 0) + \phi(t, x)F_\tau(t),
\]

\[
-289-
\]
\[ z^\tau(0, x) = 0, \]  

where \( F_\tau(t) = \begin{cases} 
  u_{xx}^\tau(t, 0) - u_{0}^\tau(0), & t \leq \tau, \\
  u_{xx}^\tau(t, 0) - u_{xx}^\tau(t - \tau, 0), & t > \tau. 
\end{cases} \]

Let \( t \leq \tau \). By initial condition (15), \( u_{xx}^\tau(0, 0) = u_{0}^\tau(0) \); by (14) and (17), \( |u_{xx}^\tau| \leq C_9 \). Thus,

\[ |F_\tau(t)| = |u_{xx}^\tau(t, 0) - u_{0}^\tau(0)| = \left| u_{xx}^\tau(0, 0) - u_{0}^\tau(0) + \int_0^t u_{xx}^\tau(\theta, 0) d\theta \right| \leq C_9 \tau, \quad 0 \leq t \leq \tau. \]

Let \( t > \tau \). By mean value theorem,

\[ |F_\tau(t)| = |u_{xx}^\tau(t, 0) - u_{xx}^\tau(t - \tau, 0)| = |u_{xx}^\tau(t, 0)| \tau \leq C_9 \tau, \quad \tau < t \leq T, \quad t - \tau \leq \theta \leq t. \]

Thus, \( F_\tau(t) \leq C_9 \tau \). Under Lemma 1,

\[ \sup_{\Pi[0, \tau]} |u^* - u| = \max_{\Pi[0, \tau]} |z^\tau(t, x)| \leq C_{10} \tau. \]

**Theorem 1.** If the conditions (16) are valid, then the Tonelli’s method converges at linear rate, i.e. \( \max_{\Pi[0, \tau]} |u^* - u| \leq C \tau \).

### 5. Weak approximation method

Let \( \tau > 0 \) be a constant such that \( N\tau = T, N \) is integer. We make a split (see [3, 5, 6]) of the problem (6), (7) to two fractional steps, making time shift by \( \tau/2 \) in trace of unknown function:

\[ \frac{\partial u^\tau}{\partial t} = 2 \frac{\partial^2 u^\tau}{\partial x^2}, \quad t \in (n\tau, (n + 1/2)\tau], \]  
\[ \frac{\partial u^\tau}{\partial t} = 2\phi(t, x) \left[ u''(t - \tau/2, x) \right], \quad t \in ((n + 1/2)\tau, (n + 1)\tau], \]  
\[ u^\tau(0, x) = u_0(x), \quad n = 0, 1, \ldots, N - 1. \]

**Remark.** The problem (23)–(25) is a particular case of problem (2.2.18) investigated in article [7]. Inequalities (17), (18), and convergence of \( u^\tau \) to \( u \) are proved.

We denote averaging function (see [3, p. 41]) as

\[ u_{cp}^\tau(t, x) = \frac{1}{\tau} \int_t^{t + \tau} u^\tau(\theta, x) d\theta. \]  

Note that \( u_{cp}^\tau(t, x) \) is defined in \( \Pi[0, T - \tau] \). By applying mean value theorem to right-hand side of (26) \( u_{cp}^\tau(t, x) \) is continuous function of \( t \),

\[ u_{cp}^\tau(t, x) = \frac{1}{\tau} \int_t^{t + \tau} u^\tau(\theta, x) d\theta = u^\tau(\xi, x), \quad t \leq \xi < t + \tau. \]

\[ \frac{\partial^2}{\partial x^2} u_{cp}^\tau(t, x) = \frac{1}{\tau} \int_t^{t + \tau} u_{xx}^\tau(\theta, x) d\theta = u_{xx}^\tau(\xi, x), \quad t \leq \xi < t + \tau. \]
By (17), \( u^\tau \) and \( u^\tau_{xx} \) are satisfying Lipschitz condition with respect to \( t \), thus

\[
|u^\tau_{cp}(t, x) - u^\tau(t, x)| = |u^\tau(\xi, x) - u^\tau(t, x)| \leq C_0|\xi - t| \leq C_0\tau,
\]

\[
\left| \frac{\partial^2}{\partial x^2} u^\tau_{cp}(t, x) - u^\tau_{xx}(t, x) \right| = |u^\tau_{xx}(\xi, x) - u^\tau_{xx}(t, x)| \leq C_0|\xi - t| \leq C_0\tau.
\]  

(27)

We apply averaging function to the problem (23)–(25):

\[
\frac{\partial u^\tau_{cp}}{\partial t} = \frac{\partial^2 u^\tau_{cp}}{\partial x^2} + \phi(t, x) \left( \varphi'(t) - \frac{\partial^2 u^\tau_{cp}}{\partial x^2}(t, 0) \right) + F_\tau(t, x), \quad (t, x) \in \Pi_{[0, T - \tau]},
\]

(28)

where

\[
F_\tau(t, x) = \frac{1}{\tau} \int_t^{t + \tau} \left\{ \alpha_1, \tau(\theta)u^\tau_{xx}(\theta, x) + \alpha_2, \tau(\theta)\phi(\theta, x) [\varphi'(\theta) - u^\tau_{xx}(\theta - \tau/2, x)] - \right. \\
\left. - \frac{\partial^2 u^\tau_{cp}}{\partial x^2}(t, x) - \phi(t, x) \left[ \varphi'(t) - \frac{\partial^2 u^\tau_{cp}}{\partial x^2}(t, 0) \right] \right\} d\theta,
\]

(30)

\[
\alpha_1, \tau(t) = \begin{cases} 2, & t \in (n\tau, (n + 1/2)\tau], \\ 0, & t \in ((n + 1/2)\tau, (n + 1)\tau], \end{cases} \quad \alpha_2, \tau(t) = \begin{cases} 0, & t \in (n\tau, (n + 1/2)\tau], \\ 2, & t \in ((n + 1/2)\tau, (n + 1)\tau]. \end{cases}
\]

Note that the term

\[
\Psi(t, x) = \frac{\partial^2 u^\tau_{cp}}{\partial x^2}(t, x) + \phi(t, x) \left[ \varphi'(t) - \frac{\partial^2 u^\tau_{cp}}{\partial x^2}(t, 0) \right]
\]

in the integrand of \( F_\tau(t, x) \) (30) does not depend on \( \theta \), \( \int_t^{t + \tau} \alpha_1, \tau(\theta)d\theta = \int_t^{t + \tau} \alpha_2, \tau(\theta)d\theta = 1 \), thus

\[
\int_t^{t + \tau} \Psi(t, x)d\theta = \int_t^{t + \tau} \left\{ \alpha_1, \tau(\theta) \frac{\partial^2 u^\tau_{cp}}{\partial x^2}(t, x) + \alpha_2, \tau(\theta)\phi(t, x) \left[ \varphi'(t) - \frac{\partial^2 u^\tau_{cp}}{\partial x^2}(t, 0) \right] \right\} d\theta.
\]

Interval of integration \([t, t + \tau]\) is split by points \( \{j\tau/2\}, j = 0, \ldots, 2N - 1 \) to three parts (or two, if \( t \) is exactly \( j\tau/2 \)). Let \( I_s, s = 1, 2 \) be subsets of interval \([t, t + \tau]\) such that \( \alpha_s, \tau(\theta) \neq 0, \theta \in I_s \).

We rewrite (30) as

\[
F_\tau(t, x) = \frac{2}{\tau} \int_{I_1} \left( u^\tau_{xx}(\theta, x) - \frac{\partial^2 u^\tau_{cp}}{\partial x^2}(t, x) \right) d\theta + \\
+ \frac{2}{\tau} \int_{I_2} \left( \phi(t, x)[\varphi'(\theta) - u^\tau_{xx}(\theta - \tau, 0)] - \phi(t, x) \left[ \varphi'(t) - \frac{\partial^2 u^\tau_{cp}}{\partial x^2}(t, 0) \right] \right) d\theta.
\]

(31)

From (31)

\[
\left| u^\tau_{xx}(\theta, x) - \frac{\partial^2 u^\tau_{cp}}{\partial x^2}(t, x) \right| \lesssim \left| u^\tau_{xx}(\theta, x) - u^\tau_{xx}(t, x) \right| + \left| u^\tau_{xx}(t, x) - \frac{\partial^2 u^\tau_{cp}}{\partial x^2}(t, x) \right| \lesssim \\
\lesssim u^\tau_{xx}(\xi, x) |\theta - t| + C_0\tau \lesssim C_11\tau, \quad t \leq \xi \leq \theta \leq t + \tau.
\]
We estimate the second term in \( F_t(t, x) \):

\[
\left| \phi(\theta, x)[\varphi'(\theta) - u_{xx}^\tau(\theta - \tau, 0)] - \phi(t, x)[(\varphi'(t) - \frac{\partial^2 u_{cp}^\tau}{\partial x^2}(t, 0)) \right| \\
\leq \left| \phi(\theta, x)[\varphi'(\theta) - u_{xx}^\tau(\theta - \tau, 0)] - \phi(\theta, x)[\varphi'(\theta) - u_{xx}^\tau(\theta, 0)] \right| + \\
+ \left| \phi(\theta, x)[\varphi'(\theta) - u_{xx}^\tau(\theta, 0)] - \phi(t, x)[\varphi'(t) - u_{xx}^\tau(t, 0)] \right| + \\
+ \left| \phi(t, x)[\varphi'(t) - u_{xx}^\tau(t, 0)] - \phi(t, x)[\varphi'(t) - \frac{\partial^2 u_{cp}^\tau}{\partial x^2}(t, 0)) \right|.
\] (32)

By applying the mean value theorem to (32), considering (16), (17), (27) we prove \( |F_t(t, x)| \leq C_{12} \tau \). By differentiation (31) two times with respect to \( x \) and applying same reasoning we prove \( \left| \frac{\partial^2}{\partial x^2} F_t(t, x) \right| \leq C_{13} \tau \).

By substraction (6), (7) from (28), (29) (here \( z^\tau = u_{cp}^\tau - u \)),

\[
\frac{\partial z^\tau}{\partial t} - \frac{\partial^2 z^\tau}{\partial x^2} - \phi(t, x)z_{xx}^\tau(t, 0) + F_t(t, x), \quad (t, x) \in \Pi_{[0, T - \tau]},
\]

\[
z^\tau(0, x) = 0.
\]

Under Lemma 1,

\[
|z^\tau(t, x)| \leq C_{13} \tau, \quad (t, x) \in \Pi_{[0, T - \tau]}.
\]

Note that \( z^\tau(t, x) \in C^{0,4}_{\Pi_{[0, T - \tau]}} \) and by (18) \( |z^\tau_t(t, x)| \leq C_9 \), thus \( |z^\tau(t, x)| \leq C_{13} \tau \) for \( (t, x) \in \Pi_{[0, T]} \).

By this, (27), and the triangle inequality,

\[
|u^\tau - u| \leq |u^\tau - u_{cp}^\tau| + |u_{cp}^\tau - u| \leq C_{14} \tau.
\]

We finally proved

**Theorem 2.** *If the conditions (16) are valid, then weak approximation method converges at linear rate in domain \( \Pi_{[0, T]} \).*

### 6. Future research

One can prove the Lemma 1 in multidimensional case, i.e. for problem

\[
\frac{\partial z^\tau}{\partial t} = \Delta z^\tau(t, x) + B(z^\tau) + F_t(t, x),
\]

\[
z^\tau(0, x) = 0
\]

in domain \( \Pi_{[0, T]} = \{(t, x) | 0 \leq t \leq T, x \in E^n, n > 1 \} \), where \( B(z) \) is a linear operator with coefficients of \( C^{0,2}_{\Pi_{[0, T]}} \) class, depending on function \( z \), its first-order partial derivatives, and traces of partial derivatives up to second order. For example,

\[
B(z^\tau) = z^\tau(t, x) + \sin(tx_1x_2 \ldots x_n)z^\tau(t, 0) + \sum_{i=1}^n z_{xx}^\tau(t, 0) + \Delta z^\tau(t, 0).
\]

This will provide a method for proving linear rate of convergence of weak approximation method for a range of inverse problems.
Example. The inverse problem

$$u_t = \Delta u + \sum_{i=1}^{n} u_{x_i} + \mu(t)u + f(t, x), (t, x) \in \Pi_{[0,T]},$$

$$u(0, x) = u_0(x),$$

$$u(t, 0) = \phi(t),$$

with unknown \(\mu(t)\), reduces to a Cauchy problem for a loaded equation

$$u_t = \Delta u + \sum_{i=1}^{n} u_{x_i} + \frac{\phi'(t) - \Delta u(t, 0) - \sum_{i=1}^{n} u_{x_i}(t, 0) - f(t, 0)}{\phi(t)} u + f(t, x),$$  \(35\)

$$u(0, x) = u_0(x).$$  \(36\)

Provided \(f(t, x) \in C^{0,0}(\Pi_{[0,T]}), u_0(x) \in C^{0}(\mathbb{E^n}), \phi(t) \in C^2([0,T]),\) one can use weak approximation method to above problem, by splitting (35), (36) to fractional steps

$$u^\tau_t = \alpha_{1, \tau}(t) \left[ \Delta u^\tau + \sum_{i=1}^{n} u^\tau_{x_i} + f(t, x) \right] +$$

$$+ \alpha_{2, \tau}(t) \left[ \frac{\phi'(t) - \Delta u^\tau(t - \frac{T}{2}, 0) - \sum_{i=1}^{n} u^\tau_{x_i}(t - \frac{T}{2}, 0) - f(t, 0)}{\phi(t)} u^\tau \right],$$  \(37\)

$$u^\tau(0, x) = u_0(x),$$  \(38\)

proving boundedness \([4]\) of derivatives of \(u^\tau\) with respect to \(x_i\) up to sixth order, proving convergence of \(u^\tau\) to \(u\). As in Section 4, by subtraction of (35), (36) from the split-problem and applying averaging function, one can write down the problem for function \(z^\tau = u^\tau - u:\)

$$z^\tau_t = \Delta z^\tau + B(z^\tau) + F_\tau(t, x),$$

$$z^\tau(0, x) = 0,$$

where

$$B(z^\tau) = \sum_{i=1}^{n} z^\tau_{x_i}(t, x) + \frac{\phi'(t) - f(t, 0)}{\phi(t)} z^\tau(t, x) + \frac{\Delta u^\tau(t, 0) - \sum_{i=1}^{n} u^\tau_{x_i}(t, 0)}{\phi(t)} z^\tau(t, x) -$$

$$- \frac{u(t, x)}{\phi(t)} \Delta z^\tau(t, 0) - \frac{u(t, x)}{\phi(t)} \sum_{i=1}^{n} z^\tau_{x_i}(t, 0),$$

and \(F(t, x) \in C^{0,2}(\Pi_{[0,T]}\) is a function satisfying the conditions of Lemma 1. Thus one can prove linear rate of convergence of weak approximation method in this case.

Рассматривается задача Коши для нагруженного уравнения в частных производных, возникающая при решении коэффициентных обратных задач. Ранее доказана сходимость метода Тонелли и метода слабой аппроксимации для рассматриваемой задачи. В работе доказывается первый порядок сходимости данных методов.

Ключевые слова: дифференциальные уравнения, обратная задача, задача Коши, метод Тонелли, метод слабой аппроксимации.
